Document Object Model (DOM)

- The data structure the browser uses to represent the document follows this shape.
- For each box, there is an object, which we can interact with to find out things such as what HTML tag it represents and which boxes and text it contains.
- This representation is called the Document Object Model, or DOM for short.
- The JavaScript global binding, document, gives us access to these objects.
- Its documentElement property refers to the object representing the <html> tag.
- Since every HTML document has a head and a body, …
- … it also has head and body properties, pointing at those elements.
